

CLAIMS

We claim:

1. A method of coordinating slotted multiple access in a wireless network channel shared by a plurality of users comprising the steps of utilizing a polling mode, utilizing a contention mode and utilizing a seamless transition between the polling and contention modes to coordinate user transmission.

2. The method of claim 1 further comprising assigning each of a plurality of users a distinct address from an address pool.

3. The method of claim 2 wherein the address pool contains  $2^k$  addresses, the maximum number of users within one channel.

4. The method of claim 2 further comprising dynamically splitting the address pool into  $2^x$  subgroups.

5. The method of claim 4 further comprising transmitting only the users belonging to a specific subgroup at any transmission opportunity.

6. The method of claim 5 further comprising starting of a multiple access cycle where  $x$  could be any number from 0 to  $k$ .

7. The method of claim 6 wherein the contention mode occurs when  $x=0$  and only one subgroup exists allowing every user to transmit.

1           8.           The method of claim 6 wherein the polling mode occurs when  $x=k$  and  
2           there are  $2^k$  subgroups containing only one user.

1           9.           The method of claim 6 wherein the seamless transition between the  
2           polling mode and the contention mode occurs by changing the  $x$  parameter.

1           10.          The method of claim 1 further comprising applying a contention  
2           resolution algorithm when a user signal collides with another.

1           11.          The method of claim 10 wherein when a collision occurs between two  
2           users the subgroup  $x$  will be split into two subgroups ( $x=x+1$ ), both subgroups  
3           containing half the number of users in the parent groups.

1           12.          The method of claim 10 wherein when another collision between two  
2           user signals occurs, the subgroup will again split.

1           13.          The method of claim 10 wherein when collisions no longer occur in any  
2           subgroup, the multiple access cycle ends and a new cycle begins.

1           14.          An apparatus for coordinating slotted multiple access in a wireless  
2           network channel shared by a plurality of users comprising:

- 3           a.           means for implementing a polling mode to facilitate user  
4           transmission when there is one user in every subgroup;  
5           b.           means for implementing a contention mode to facilitate user  
6           transmission when there are no subgroups; and  
7           c.           means for providing a seamless transition between the polling  
8           and contention modes to coordinate user transmission.

1           15.           The apparatus of claim 14 further including means for assigning each of  
2 a plurality of users a distinct address from an address pool.

1           16.           The apparatus of claim 15 wherein the address pool contains  $2^k$   
2 addresses, the maximum number of users within one channel.

1           17.           The apparatus of claim 15 further including means for dynamically  
2 splitting the address pool into  $2^x$  subgroups.

1           18.           The apparatus of claim 17 further including means for transmitting only  
2 the users belonging to a specific subgroup at any transmission opportunity.

1           19.           The apparatus of claim 18 further including means for starting of a  
2 multiple access cycle where x could be any number from 0 to k.

1           20.           The apparatus of claim 19 wherein the contention mode occurs when  
2  $x=0$  and only one subgroup exists allowing every user to transmit.

1           21.           The apparatus of claim 19 wherein the polling mode occurs when  $x=k$   
2 and there are  $2^k$  subgroups containing only one user.

1           22.           The apparatus of claim 19 wherein the seamless transition between the  
2 polling mode and the contention mode occurs by changing the x parameter.

1           23.           The apparatus of claim 14 further including means for applying a  
2 contention resolution algorithm when a user signal collides with another.

1 24. The apparatus of claim 23 wherein when a collision occurs between two  
2 users the subgroup  $x$  will be split into two subgroups ( $x=x+1$ ), both subgroups  
3 containing half the number of users in the parent groups.

1 25. The apparatus of claim 23 wherein when another collision between two  
2 user signals occurs, the subgroup will again split.

1 26. The apparatus of claim 23 wherein when collisions no longer occur in  
2 any subgroup, the multiple access cycle ends and a new cycle begins.

1 27. An apparatus for coordinating slotted multiple access in a wireless  
2 network channel shared by a plurality of users comprising:

- 3 a. an ATM cube for operating a high speed wireless network  
4 consisting of a plurality of horizontal and vertical management layers;  
5 b. a hub for transmitting and receiving wireless network signals  
6 such that the hub may receive requests and assign portions of a  
7 communication bandwidth; and  
8 c. a plurality of end user nodes for transmitting and receiving  
9 wireless network signals such that a plurality of users may request or be  
10 granted a portion of the communication bandwidth.

1 28. The apparatus of claim 27 wherein the hub assigns each of a plurality  
2 of users a distinct address from an address pool.

1 29. The apparatus of claim 28 wherein the address pool contains  $2^k$   
2 addresses, the maximum number of users within one channel.

1 30. The apparatus of claim 28 wherein the address pool may be  
2 dynamically split into  $2^x$  subgroups.

1 31. The apparatus of claim 30 wherein at any transmission opportunity only  
2 the users belonging to a specific subgroup transmit.

1 32. The apparatus of claim 31 wherein the hub starts a multiple access  
2 cycle where  $x$  could be any number from 0 to  $k$ .

1 33. The apparatus of claim 32 wherein the contention mode occurs when  
2  $x=0$  and only one subgroup exists allowing every user to transmit.

1 34. The apparatus of claim 32 wherein the polling mode occurs when  $x=k$   
2 and there are  $2^k$  subgroups containing only one user.

1 35. The apparatus of claim 32 wherein the seamless transition between the  
2 polling mode and the contention mode occurs by changing the  $x$  parameter.

1 36. The apparatus of claim 27 wherein the hub implements a contention  
2 resolution algorithm when a user signal collides with another.

1 37. The apparatus of claim 36 wherein when a collision occurs between two  
2 users the subgroup  $x$  will be split into two subgroups ( $x=x+1$ ), both subgroups  
3 containing half the number of users in the parent groups.

1 38. The apparatus of claim 36 wherein when another collision between two  
2 user signals occurs, the subgroup will again split.
